We investigate all pure quantum-electrodynamics corrections to the np → 1s, n = 2 – 4 transition energies of pionic hydrogen larger than 1 meV, which requires an accurate evaluation of all relevant contributions up to order α³. These values are needed to extract an accurate strong interaction shift from experiment. Many small effects, such as second order and double vacuum polarization contribution, proton and pion self-energies, finite size and recoil effects are included with exact mass dependence. Our final value differs from previous calculations by up to ≈9 ppm for the 1s state, while a recent experiment aims at a 4 ppm accuracy.

I. INTRODUCTION

Pion-Nucleon scattering lengths are quantities of fundamental importance in low-energy hadronic physics. For the 1s state of pionic hydrogen (πH), the low energy scattering lengths at threshold aπ−p→π−p and aπ−p→πνn are connected to ε₁s and Γ₁s, the hadronic shift and broadening, through Deser formula [1]

\[
\frac{\epsilon_{1s}}{E_{1s}} = \frac{4}{r_B} a_{\pi^- p \to \pi^- p} (1 + \delta_{\pi}) \\
\frac{\Gamma_{1s}}{E_{1s}} = \frac{8Q_0}{r_B} \left( 1 + \frac{1}{P} \right) (a_{\pi^- p \to \pi \nu n} (1 + \delta_{\pi}))^2
\]

where E₁s is the 1s binding energy. The Bohr radius rₐ is given by

\[
r_B = \frac{1}{\mu a Z},
\]

where \(\alpha \approx 1/137.036\) is the fine structure constant and Z the atomic number. The quantities δₚ and δπ are corrections due to the distortion of the pion wavefunction by the strong interaction, \(Q_0 = 0.142 \text{ fm}^{-1}\) is the momentum of the π⁰ in the center of mass system and \(P = 1.546 \pm 0.009\) is the Panofski ratio of scattering amplitudes \(a_{\pi^- p \to \pi^- p}\) and \(a_{\pi^- p \to \pi \nu n}\), which is derived from experiment [2].

Determination of accurate values of the scattering length allow for tests of Chiral perturbation theory—the low energy approach to QCD — in particular for the extraction of chiral symmetry breaking parameters [3–6] as well as for tests of the other approaches [7–10]. The strong interaction shift \(\epsilon_{1s}\) is obtained by comparing theoretical, pure QED transition energies to the measured np → 1s ones. There are many issues involved in the derivation of the physically meaningful scattering amplitudes from the experimentally measurable parameters \(\epsilon_{1s}\) and \(\Gamma_{1s}\). These issues are mainly connected to the accuracy with which one can disentangle QED and QCD contributions (see, e.g., [6, 11] for recent reviews). In the case of \(a_{\pi^- p \to \pi^- p}\), the QED/QCD separation is present in both the extraction of \(\epsilon_{1s}\) from experimental transition energies and in the evaluation of \(\delta_{\pi}\). The strong interaction shift is a correction of order \(\alpha^3\) to the usual Coulomb binding energy of the 1s level. It was evaluated in leading order in Chiral perturbation theory [3] and in next to leading order in [5]. The ground state energy shift is written as [3]

\[
\epsilon_{1s} = -2\alpha^3 \mu^2 A \left( 1 - 2\alpha (\ln \alpha - 1)\mu A \right) + \ldots
\]

in term of the \(\pi^- p \to \pi^- p\) scattering amplitude at threshold \(A\). Here \(\frac{1}{\mu} = \frac{1}{m_\pi} + \frac{1}{m_p}\) is the reduced mass, \(m_\pi\), \(m_p\) denoting the charged pion and proton masses respectively. The scattering amplitude at threshold is connected to the isospin-invariant amplitudes \(a_{0^+}^+\) and \(a_{0^+}\) as

\[
A = a_{0^+}^+ + a_{0^+} + \epsilon
\]

where \(\epsilon\) is the isospin-symmetry breaking term due to the electromagnetic interaction. The evaluation of \(\epsilon\) is required to derive \(a_{0^+}^+\) and \(a_{0^+}\) from experiment. The scattering length \(a_{0^+}^+\) and \(a_{0^+}\) are calculated in an isospin-symmetric theory with no electromagnetic interaction and identical masses for the up and down quarks. With this convention one obtains at order \(O(p^2)\) [3]:

\[
\epsilon = \frac{m_p}{8\pi (m_p + m_\pi)} F_\pi^2 \left\{ 8c_1 (m_\pi^2 - m_{\pi^0}^2) - 4\epsilon f_1 - \epsilon^2 f_2 \right\},
\]

where \(m_\pi^0\) is the mass of the neutral pion, \(\epsilon\) the electric charge, \(F_\pi = 92.4\text{ MeV}\) the pion decay constant and \(c_1, f_1, f_2\) are the low energy constants of the phenomenological chiral pion-nucleon interaction Lagrangian. Two of

Quantum-electrodynamics corrections in pionic hydrogen

S. Schlesser,¹,* E.-O. Le Bigot,¹ P. Indelicato,¹,† and K. Pachucki²

¹Laboratoire Kastler Brossel, École Normale Supérieure, CNRS, Université Pierre et Marie Curie-Paris 6, Case 744, 4 place Jussieu, F-75005 Paris, France
²Faculty of Physics, University of Warsaw, Hoża 69, 00-681, Warsaw, Poland

(Dated: May 14th, 2011)
the low-energy constants $c_1 = -0.9^{+0.2}_{-0.5}$ GeV$^{-1}$ [6] and $\epsilon^2 f_2 = -(0.97 \pm 0.38)$ MeV [6] can be derived from experiment. The determination of $f_1$ value, however, is more problematic and leads to the largest uncertainty in the determination of $D_{p0}^2$ and $D_{p0}^0$ from $\epsilon_{1s}$ [5, 6]. An uncertainty of 100 MeV represents a contribution to determination of $f_1$, however, are also present in the pionic deuteron energy shift and can be eliminated in the determination of the isospin symmetric scattering length[11, 12]. The deuteron shift was measured in several experiments [13–15].

The most accurate present experimental values from pionic hydrogen are $\epsilon_{1s} = -7.108 \pm 0.013$ (stat.) $\pm 0.034$ (syst.) eV and $\Gamma_{ns} = 0.868 \pm 0.040$ (stat.) $\pm 0.038$ (syst.) eV [16, 17]. A recent experiment [18] at the Paul Scherrer Institute aims at a $\approx 4$ ppm accuracy ($\approx 0.01$ eV) on transition energies, leading to a determination of the strong interaction shift to better than 1%, if compared to accurate QED results. In this work, we evaluate all QED contributions to the $1\to 0$ transition in what concerns the proton radius is at the moment complicated. There is a recent very accurate value from Refs. [20], while the pion mass $(139.57018(35)$ MeV) and charge radius $(0.672(8)$ fm) come from [21]. The situation in what concerns the proton radius is at the moment complicated. There is a recent very accurate value from muonic hydrogen $0.84184(67)$ fm [22], that is 5 standard deviations away from the one obtained from hydrogen $0.8768(69)$ fm [20] and from the most recent electron-proton elastic scattering $0.879(8)$ fm [23]. Here we use the muonic hydrogen value, as the pion and muon mass are close, and whatever effect is at play in this large discrepancy, must be more likely to be identical between muonic and pionic hydrogen.

\[ E_{\text{KC}}(Z, n, l) = \left( \frac{1 + \frac{(Z\alpha)^2}{n - l - \frac{1}{2} + \sqrt{(l + \frac{1}{2})^2 - (Z\alpha)^2}}}{1} \right)^{-\frac{1}{4}} - 1 \mu e^2, \]  

II. QED CALCULATION

A. Breit equation including Darwin term and magnetic moment

The Breit-Pauli Hamiltonian for our system is [24, 25] $H_{\text{BP}} = H_0 + \delta H + V_{\text{BP}}$ with

\[ H_0 = \frac{\mu^2}{2\mu} Z\alpha \frac{1}{r}, \quad \delta H = -\frac{p^4}{8m^3_{\pi}} - \frac{p^4}{8m^3_{\nu}} \]  

\[ V_{\text{BP}} = \frac{\pi Z\alpha}{2} \frac{1}{m^2_{\pi}} \delta^3(r) - \frac{Z\alpha}{2m_{\nu}m_{\pi}} p^2 \frac{1}{r} \left( \delta_{ij} + \frac{r_i r_j}{r^2} \right) \]  

\[ + Z\alpha \frac{1 + 2\kappa}{4m^2_{\pi}} + \frac{1 + \kappa}{2m_{\nu}m_{\pi}} \delta_\nu \delta_\pi \]  

\[ + \frac{2}{3} Z\alpha \left( \langle r^2_z \rangle + \langle r^2_\nu \rangle \right) \delta^3(r). \]

Here $\langle r^2_z \rangle$ and $\langle r^2_\nu \rangle$ are the mean square charge radii of the pion and proton, $\kappa$ is the proton magnetic moment anomaly, $\sigma$ are Pauli matrices and $Z$ is the nuclear charge, which is used to distinguish proton and pion contributions. The corresponding QED diagrams are shown on Fig. 1. We note that the pion Darwin term, $\frac{1}{m\pi^2} \delta^3(r)$ is absent because the spin of the pion is 0. The known $\frac{\pi Z\alpha}{2} \frac{(2\kappa)}{m^2_{\pi}} \delta^3(r)$ magnetic anomaly correction to the first term in (8) is in this case included in the proton charge distribution (9), when provided by bound-state measurements [26, 27], from which is derived the proton charge radius [22]. The corresponding energies for each contribution can be found in Ref. [25] for example.

A complete relativistic treatment of the pion bound states, in the non-recoil approximation, can be done in the framework of the Klein-Gordon equation. The corresponding energy is given by the well known expression

\[ E_{\text{KG}}(Z, n, l) = \left( 1 + \frac{(Z\alpha)^2}{n - l - \frac{1}{2} + \sqrt{(l + \frac{1}{2})^2 - (Z\alpha)^2}} \right)^{-\frac{1}{4}} - 1 \mu e^2, \]
which can be expanded in power of $Z\alpha$ as
\[
E_{\text{KG}}(Z,n,l) = \frac{(Z\alpha)^2}{2\pi^2} \mu \omega^2 \quad (11)
\]
\[
+ \frac{3}{8n^2} - \frac{1}{(2l+1)n^4} (Z\alpha)^4 \mu \omega^2
\]
\[
+ \mathcal{O}((Z\alpha)^6). \quad (12)
\]
The two first term of this expansion are included in the solutions of (7) and (8). We include the sum of all higher-order terms in our result for completeness.

B. Vacuum polarization corrections

The electron vacuum polarization modifies the effective electromagnetic interaction. Because of the relatively large pion mass, diagrams with vacuum polarization loops dominate among QED corrections, while the self-energy is very small, in contrast to electronic atoms. The vacuum polarization can be evaluated by modifying the photon propagator. In leading order, it corresponds to the replacement:
\[
- \frac{g_{\mu\nu}}{k^2} \rightarrow - \frac{g_{\mu\nu}}{k^2} (1 - \tilde{\omega}(k^2)). \quad (13)
\]
At the one-loop level, $\tilde{\omega}$ is given by [28]:
\[
\tilde{\omega}(k^2) = \frac{\alpha}{\pi} k^2 \int_{q_0}^{\infty} d(q^2) \frac{1}{q^2(m^2_e q^2 - k^2)} u(q^2), \quad (14)
\]
with
\[
u(q^2) = \frac{1}{3} \sqrt{1 - \frac{4}{q^2} \left(1 + \frac{2}{q^2}\right)}. \quad (15)
\]
This leads to the effective interaction potential (Fig. 2):
\[
V_{\text{vp}}(r) = \frac{Z\alpha}{r} \int_{q_0}^{\infty} d(q^2) \frac{1}{q^2} e^{-m_\pi q r} u(q^2), \quad (16)
\]
known as the Uehling potential [29]. The corresponding energy shift in the first order is:
\[
E_{\text{nl}} = \langle \phi_{\text{nl}} | V_{\text{vp}} | \phi_{\text{nl}} \rangle = \int d^3 r V_{\text{vp}}(r) |\phi_{\text{nl}}(r)|^2, \quad (17)
\]
where $\phi_{\text{nl}}(r)$ is the Schrödinger-Coulomb wavefunction [30], which depends on the reduced mass $\mu$. Replacing (16) in (17) leads to:
\[
E_{\text{nl}} = -Z\alpha \frac{\alpha}{\pi} \int_{q_0}^{\infty} d(q^2) \frac{1}{q^2} u(q^2) \int dr e^{-m_\pi q r} R_{\text{nl}}^2(r), \quad (18)
\]
where the integral over $r$ is performed analytically and $R_{\text{nl}}$ is the radial part of $\phi_{\text{nl}}$. In the case of the 1s level the integral over $q^2$ can also be evaluated analytically.

The muonic vacuum polarization (in which the $e^+e^-$ loop is replaced by a $\mu^+\mu^-$ loop) is evaluated by replacing the electron mass $m_e$ by the muon mass in Eq. (16).

In order to achieve a few ppm accuracy, we also calculate the leading relativistic correction to the nonrelativistic electronic vacuum polarization contribution, which is done, in the framework of the Breit-Pauli approach, with the exact mass dependence, representing the interaction between the particles by the exchange of a massive photon. We integrate over this mass $q$ which is equivalent, through dispersion relation, to integrate over $g$. Following the derivation in Ref. [31] §83 that provides Eq. (8), but using $\gamma_{\text{vp}}(r) = -\frac{g}{r} e^{-\nu r}$ instead of the Coulomb interaction, we get:
\[
V_{\text{BP}}^{\text{BP}}(r) = \frac{\alpha}{\pi} \int_{q_0}^{\infty} \frac{d(q^2)}{\sqrt{q^2}} u \left(\frac{q^2}{m_e^2}\right) \gamma_{\text{BP}}^{\text{BP}}(r), \quad (19)
\]
with
\[
\gamma_{\text{BP}}^{\text{BP}}(r) = \frac{Z\alpha}{(4\pi)^3} \frac{1}{m_p} \left(4\pi\delta(r) - \frac{\nu^2}{r} e^{-\nu r}ight)
\]
\[
- \frac{Z\alpha}{4m_p m_e} \frac{\nu^2}{r} e^{-\nu r} \left(\delta_{ij} + \frac{r_i r_j}{r^2} (1 + \nu r)\right) p^i
\]
\[
+ \frac{Z\alpha}{(4\pi)^3} \left(\frac{1 + 2\nu}{4m_p^2} + \frac{1 + \nu}{2m_p m_e}\right) e^{-\nu r} (1 + \nu r) (r \times p) \cdot \sigma. \quad (20)
\]

The hamiltonian becomes $H = H_0 + \delta H + V_{\text{BP}} + V_{\text{BP}} + V_{\text{BP}} \equiv H_0 + W$. We perform a perturbative expansion in $W$ up to second order and keep only the main terms involving the massive photon. We get:
\[
E(\varrho) = \langle \phi_{\text{nl}} | \gamma_{\text{BP}}^{\text{BP}} | \phi_{\text{nl}} \rangle
\]
\[
+ 2 \langle \phi_{\text{nl}} | (\delta H + V_{\text{BP}}) \frac{1}{(E_0 - H_0)} \gamma_{\text{BP}} | \phi_{\text{nl}} \rangle, \quad (20)
\]
which corresponds to the diagrams presented in Fig. 3. The reduced Coulomb Green function terms $G^r = \langle r_1 | (E_0 - H_0) | r_2 \rangle$ are calculated using the code written for [19]. We finally integrate over the mass $\varrho$
\[
E = \frac{\alpha}{\pi} \int_{q_0}^{\infty} \frac{d(q^2)}{\sqrt{q^2}} u \left(\frac{q^2}{m_e^2}\right) E(\varrho), \quad (21)
\]
\[ E = \langle \phi_{nl} | V_{vp}(E_0 - H_0) | \phi_{nl} \rangle. \] (22)

Two-loop vacuum polarization (Fig. 5), known as the Källén and Sabry contribution [32], involves a modified photon propagator, in the same way as the one loop one (14):

\[
\tilde{\omega}^{(2)}(-p^2) = \left(\frac{\alpha}{\pi}\right)^2 \int_4^{\infty} \frac{d(q^2)}{q^2} \frac{-p^2}{(m^2 q^2 + p^2)} u^{(2)}(q^2),
\] (23)

where the potential \( u^{(2)}(q^2) \) is given by [32]. We can proceed in a similar fashion as for the leading term, using Eq. (17), with

\[
V_{vp}^{(2)}(r) = \frac{Z\alpha}{r} \left(\frac{\alpha}{\pi}\right)^2 \int_4^{\infty} \frac{d(q^2)}{q^2} e^{-m_\pi q r} u^{(2)}(q^2),
\] (24)

We obtain:

\[
E = \langle \phi_{nl} | V_{vp}^{(2)} | \phi_{nl} \rangle = \int d^3 r \, V_{vp}^{(2)}(r) |\phi_{nl}(r)|^2.
\] (25)

\[ E_{NS}(Z\alpha, n) = \frac{2}{3} \left(\frac{\mu_r}{m_\pi}\right)^3 \frac{(Z\alpha)^4}{n^3} \frac{\langle r_P^2 + r_\pi^2 \rangle}{\lambda_C^4}, \] (26)

where \( \lambda_C = 1.4138189 \text{ fm} \) is the pion Compton wavelength. The contribution of the proton to the shift is 61.710(99) meV using the proton charge radius from [22], 66.9(11) meV using [20] and 67.3(12) meV using [23]. This contribution from the pion mass, which represents, e.g., 5.3 meV on the \( 2p - 1s \) transition.

The main corrections to the leading finite-size contribution are due to vacuum polarization, as illustrated by diagrams “a” and “b” on Fig. 6, and are given by

\[ E_a = \frac{-2}{3} \frac{\alpha}{4\pi} Z\alpha \langle r_P^2 + r_\pi^2 \rangle \int_4^{\infty} \frac{d(q^2)}{q^2} u(q^2) \times \int_0^{\infty} dr R_{nI}^2(r) \left( r (m_\pi q)^2 e^{-m_\pi q r} - \delta(r) \right), \] (27)

\[ E_b = \frac{2}{3} \frac{\alpha}{\pi} Z\alpha \langle r_P^2 + r_\pi^2 \rangle \times \int d^3 r \, \phi_{nl}(r) V_{vp}(r) G'(r,0) \phi_{nl}(0). \] (28)

\[ E_{\text{Self-energy}} \]

Except for an unpublished internal report [33], we are not aware of any calculation of the pion self-energy. We include it here. This correction correspond to the diagrams on Fig. 7. In this calculation, the part due to the high-energy contribution (which corresponds to the particle form factor) is included in the finite size, as explained for the proton case in [34]. This part must not be included in the self-energy shift to avoid double counting. The remaining low-energy part is known [28] and does
not depend on the particle spin value:

\[ E_{\pi SE} = \frac{4}{3\pi n^3} \alpha (Z\alpha)^4 \frac{\mu^3}{m_\pi^2} \times \left[ -\ln (k_0(n,l)) + \delta_{1,0} \ln \frac{m_\pi}{\mu(Z\alpha)^2} \right] \]  

(29)

where \( k_0(n,l) \) is the Bethe logarithm. The proton self-energy is obtained by replacing \( m_\pi \) by \( m_p \) and by multiplying the right-hand side of (29) by \( Z^2 \) [19, 34].

The finite size correction to the pion self-energy can be estimated from Ref. [20], Eq. (54). It is very small, even for the \( 1s \) level, and can be neglected at the present level accuracy.

**F. Additional recoil**

We can go further, evaluating the pure recoil correction of order \((Z\alpha)^5\), calculated first by Salpeter [24], which correspond to two-photon exchange (Fig. 8). In our case, there is no theoretical framework for dealing with diagrams at this level of the perturbative expansion with overlapping strong and electromagnetic interactions. Since the strong interaction overlap with the electromagnetic one only at short distances [6], we have to exclude local interactions but keep leading logarithmic parts of the contributions that wouldn’t overlap with the strong interaction. One can apply the formula from [35] which expresses the leading logarithmic term and an additional recoil term:

\[ E = \frac{(Z\alpha)^5}{\pi n^3} \frac{\mu^3}{m_pm_\pi} \left[ -\frac{2}{3} \ln(Z\alpha)\delta_{1,0} \right. \]

\[ - \frac{8}{3} \ln (k_0(n,l)) - \frac{7}{6} n^3 \left< P \left( \frac{1}{\mu_0 r^3} \right) \right>_n \]  

(30)

\( P \) is a distribution function that subtracts the singularity at the origin [35].

**G. Hadronic QED corrections**

Hadronic degrees of freedoms also contribute to the QED energy of the atom. Vacuum polarization loops with pions, for example, or the proton polarization have pure electromagnetic effects that translate into small energy shifts. One must be careful, however, as in the correction described in Sec. II F, not to calculate the contribution in the region where the QED and strong interaction correction overlaps. The hadronic polarization correction has been evaluated for hydrogen [36, 37], for muonic hydrogen by Borie [38, 39] and more recently by Friar and coll. [37] and Martynenko and Faustov [40–42], using experimental data from \( e^+ + e^- \rightarrow \) hadrons collisions. Here we use the relation

\[ E_{\text{VP}}^{\text{Hadronic}} = 0.671(15)E_{\text{VP}}^{\text{pp}} \]  

(31)

from [37], to get \(-0.1874(42)\) meV.

We do not know of any proton polarization calculation for pionic hydrogen, but it has been calculated by several authors in muonic hydrogen [19, 41–43]. Carlson and coll. have very recently calculated this correction for both the hyperfine structure of muonic hydrogen [44, 45] and for the \( 2s \) Lamb shift [46]. The value provided in Ref. [41] for the \( 1s \) state is \( 0.144 \) meV and \( 0.018 \) meV for the \( 2s \). Higher orders polarization corrections provided in [42] are negligible. Using the \( 2s \) muonic hydrogen value from Ref. [46] \( \Delta E_{\text{pp}}^{\text{pp}} = -36.9 \pm 2.4 \mu\text{eV} \), scaling it by \( n^3 = 8 \) gives \( \Delta E_{\text{pp}}^{\text{pp}} = -295 \pm 19 \mu\text{eV} \). We obtain the muonic hydrogen value by doing a scaling with the pion to muon reduced mass to the third power, we get a shift of order \(-0.62 \) meV that we use with an uncertainty of 50%. There should be an additional contribution from the pion polarizability. To account for it we increase the polarizability error to 100% of the proton value.

**III. RESULTS**

The numerical values of the corrections evaluated in Sec. II are presented in Table I, for \( 1s \), \( 2p \), \( 3p \) and \( 4p \) states and relevant hyperfine sublevels. It should be noted that if hyperfine sublevels are statistically populated, the shift due to the hyperfine interaction averages to 0 for transitions ending in an \( s \) state [48]. Adding the Schrödinger equation solution from Eq. (11) we obtain the transition energies presented in Table III, with an accuracy of \( \approx 2.3 \) ppm, dominated by the uncertainties on the pion mass (2.2 ppm, for the \( 3p \rightarrow 1s \) transition) and
the charge radii (0.5 ppm). For the 1s QED binding energy the results are presented in Table II, together with previous evaluations.

The energy of the photon emitted by an atom is slightly reduced, compared to the energy difference between the initial and final state, due to momentum and energy conservation: the atomic recoil consumes part of the available energy. Here, this correction is larger than our goal accuracy, due to the high energy of the emitted photon. The non-relativistic energy is not shown. The proton and pion size corrections are given in Eq. (26).

Using the present results and the experimental value from Ref. [17] Eq. (14), we obtain a strong interaction shift of \(-7.085 \pm 0.013\) (stat.) \(\pm 0.034\) (syst.) eV, instead of \(7.108 \pm 0.013\) (stat.) \(\pm 0.034\) (syst.) eV using the theoretical value from Ref. [7]. This does not improve much the shift accuracy (0.75%), as it is dominated by the uncertainty in the pion mass, the transition energy being calibrated with electronic K X-ray transitions in Ar. Using the preliminary value from [18, 47], which is calibrated with pionic oxygen transition energies, we get a shift of \(7.0969(96)\) (10) eV (instead of \(7.120\) eV), with a total relative accuracy of 0.14%. Because of this calibration method, which use an energy proportional to the pion mass, this new results depends only weakly on it.

In summary the present work uses non-relativistic QED techniques to provide the most accurate evaluation of pure-QED transitions energies in pionic hydrogen. Combined with recent experimental values, it allows for a significant increase in the precision of the de-

Table I. Contributions to pionic hydrogen level energies (meV), sorted by size. \(F\) is the total angular momentum. Numbers in parenthesis represent uncertainty in the last digits. When absent, the uncertainty is smaller than 1 in the last digit. The non-relativistic energy is not shown. The proton and pion size corrections are given in Eq. (26).

Table II. Theoretical QED ground state energy and comparison with previous calculations.
termination of the strong interaction shift and thus of the $\pi^-p \to \pi^-p$ scattering length at low energy. Obtaining more accurate energies would require extending effective theory like the one described in [6] to evaluate short- and electromagnetic contributions to high-orders, which is not currently possible, and an improved measurement of the pion mass. Deducing improved values of the isospin-independent scattering length from the shift would moreover require more accurate measurements of the low energy constant $f_1$.

ACKNOWLEDGMENTS

Laboratoire Kastler Brossel is “UMR n° 8552” (CNRS, ENS, UPMC). Support from UPMC for a stay in Paris of K.P. is gratefully acknowledged. This work is also partially supported by Helmholtz Alliance HA216/EMMI.

We thank D. Gotta for many suggestion and for detailed suggestions on the manuscript, B. Loiseau, T.E.O. Ericson and S. Wycech for helpful discussions.
