

Landscape of two-proton radioactivity

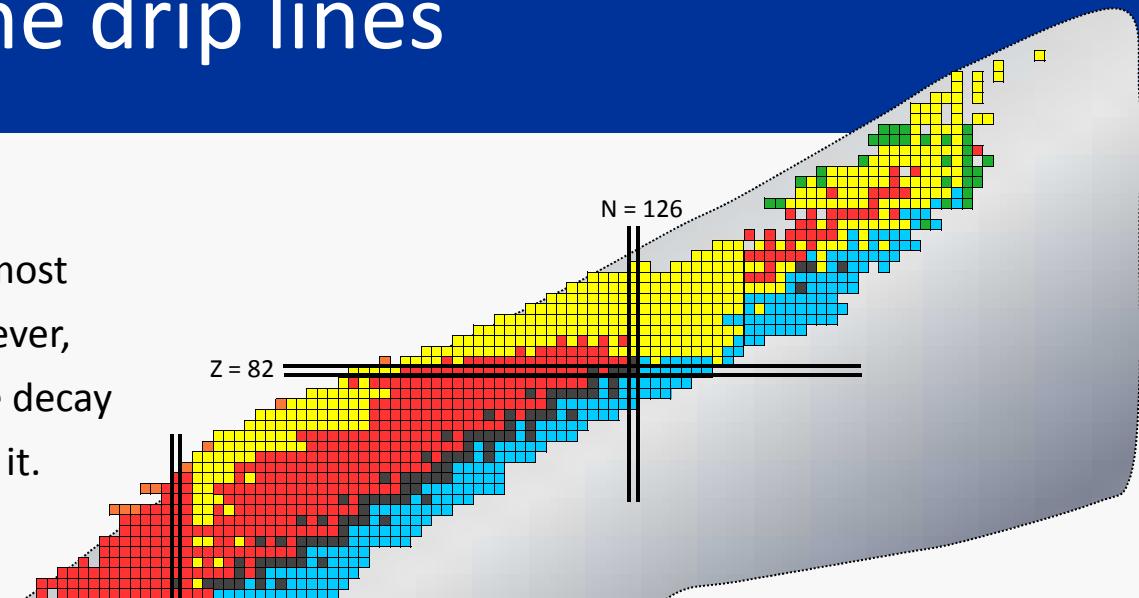

Marek Pfützner

Faculty of Physics, University of Warsaw

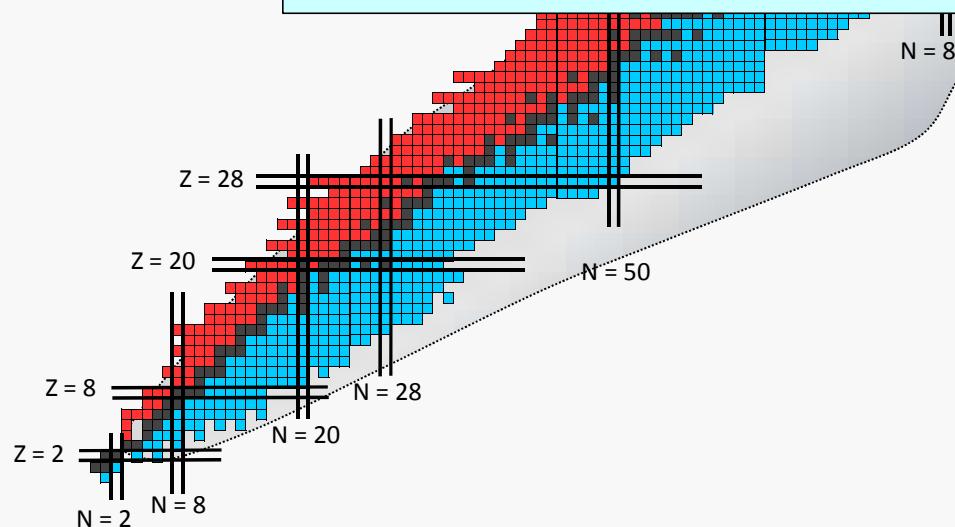

The drip lines

- The **proton drip-line** is close and almost fully delineated. In most cases, however, it is „invisible” when we cross it. The decay spectroscopy may stretch far beyond it.

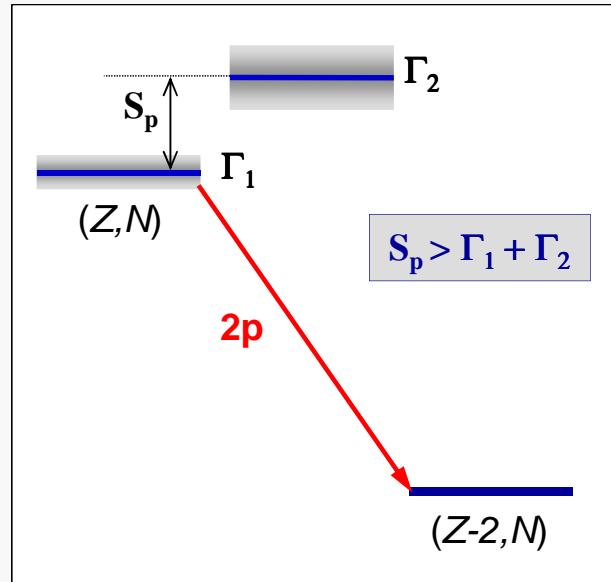

The questions: how far beyond the proton drip-line we have to go to see the difference? How far is the limit?

- The **neutron drip-line** is far from present experimental reach. It represents the real limit of decay spectroscopy – the region beyond, if accessible, is a domain of reactions.

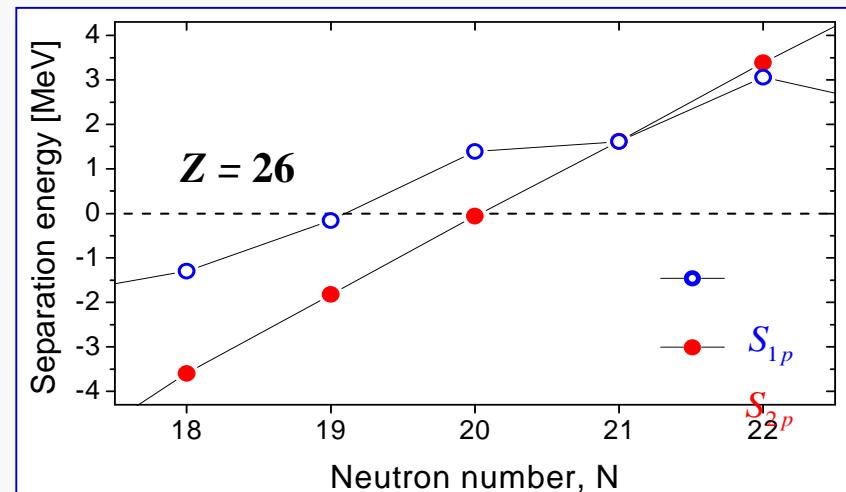

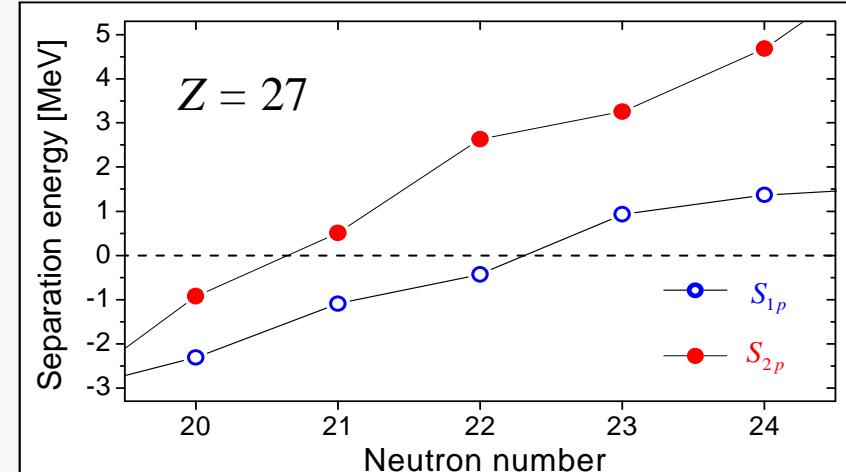

The answer for even Z

- It is possible that pair of protons is unbound while each of individual proton is bound!

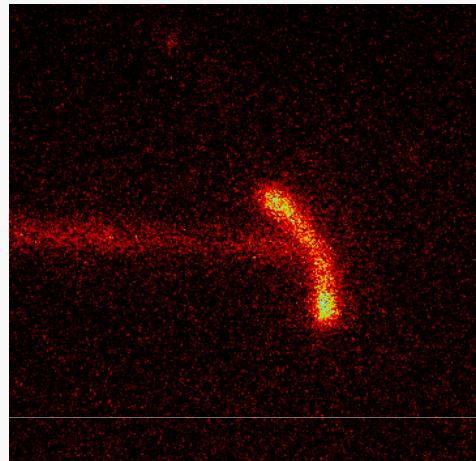

V.I. Goldanskii, Nucl. Phys. 19 (60) 482

- True 2p decay is an essentially three-body phenomenon
- It offers more information: in addition to energy and half-life, there is a distribution of protons' momenta

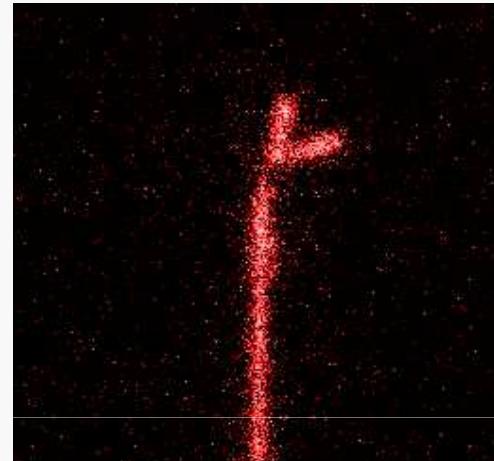

Three cases around Z=28

^{45}Fe

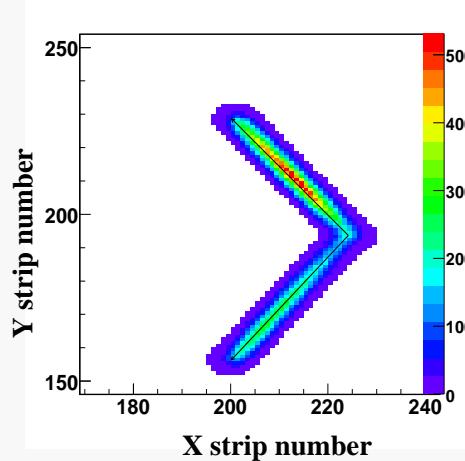

K. Miernik et al., PRL 99 (07) 192501

^{48}Ni

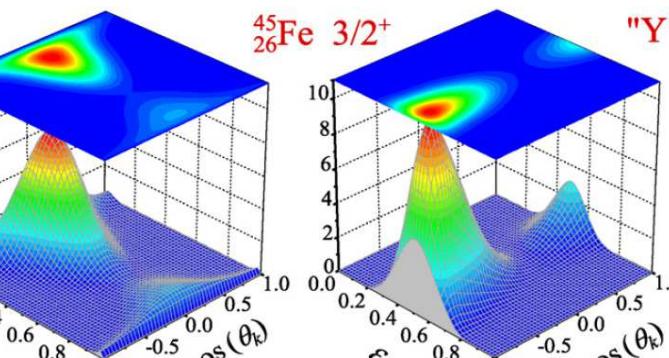

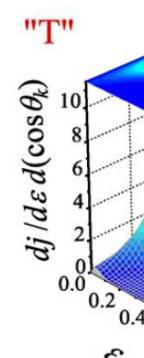

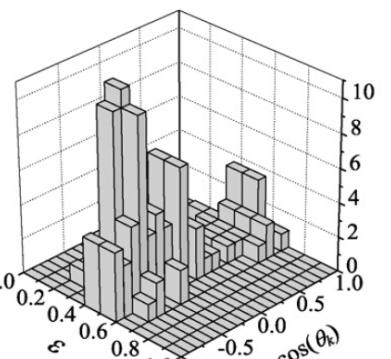

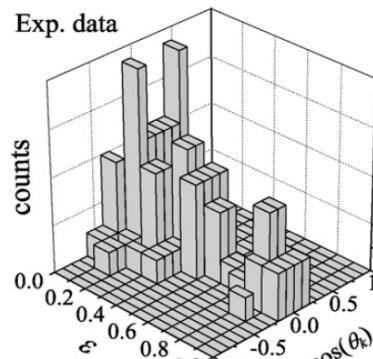

Pomorski et al., PRC 83 (2011) 061303(R)

^{54}Zn

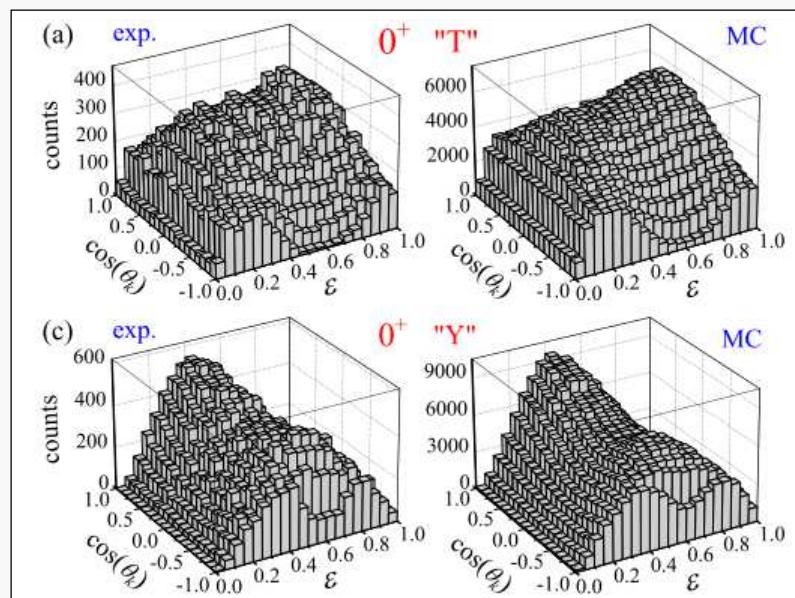

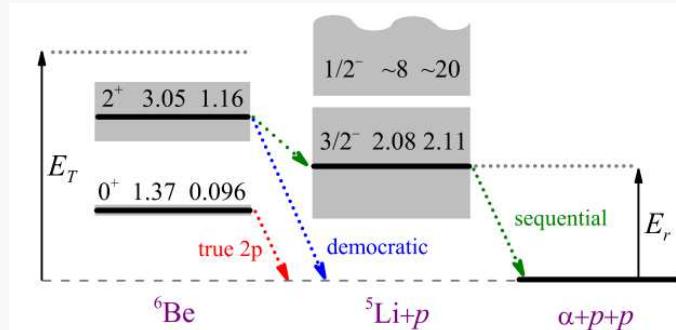

Ascher et al., PRL 107 (2011) 102502

Grigorenko et al., PLB 677 (2009) 30

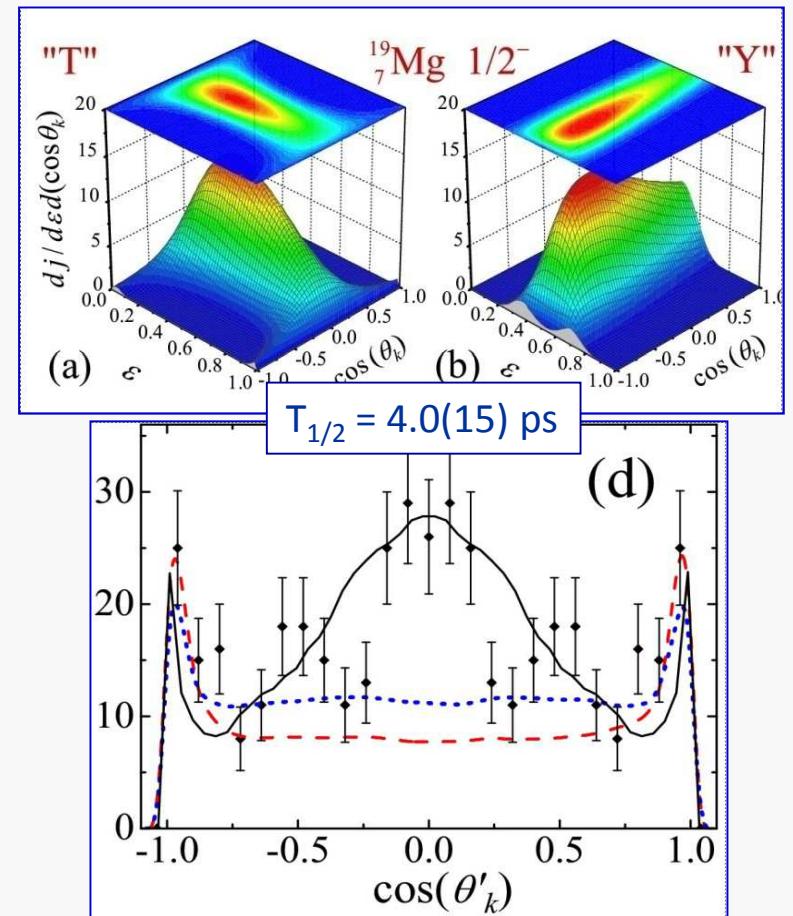

^6Be and ^{19}Mg

$^7\text{Be} + \text{Be} \rightarrow ^6\text{Be} @ \text{NSCL}$

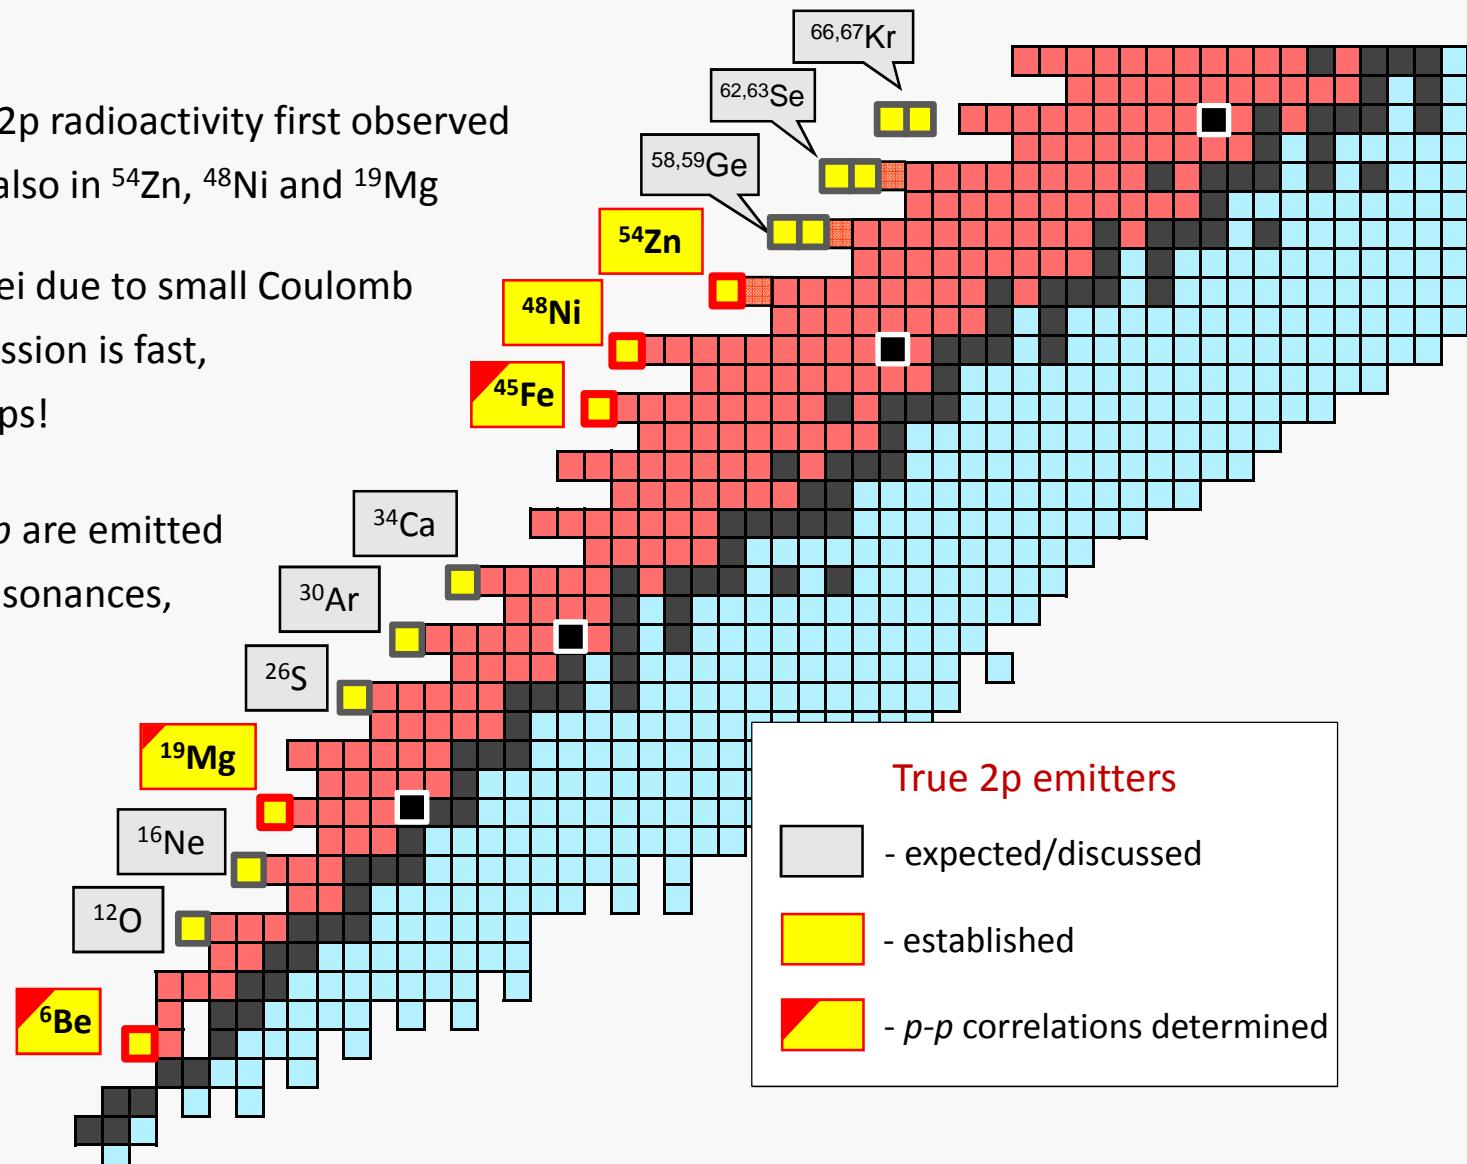

Egorova *et al.*, PRL 109 (2012) 202502

$^{20}\text{Mg} + \text{Be} \rightarrow ^{19}\text{Mg} @ \text{GSI}$

The current status of $2p$ emission

- ▶ Ground-state $2p$ radioactivity first observed in ^{45}Fe . Later also in ^{54}Zn , ^{48}Ni and ^{19}Mg
- ▶ In lighter nuclei due to small Coulomb barrier $2p$ emission is fast,
 $T_{1/2}(^{19}\text{Mg}) = 4 \text{ ps}!$
- ▶ Below ^{19}Mg $2p$ are emitted from broad resonances, like ^6Be

Heavier 2p candidates

- ▶ Proton drip-line calculations for the rp-process:
the measured masses combined with the
Coulomb displacement energies
calculated by HF with the SkX
Skyrme force

Strontium (Z=38) is the heaviest element for which the precise Q_{2p} predictions were made

Brown et al., PRC 65 (2002) 045802

Nuclear landscape

► Global mass predictions using density functional theory with **6 different Skyrme interactions**

→ There are 6900 ± 500 nuclei bound with $Z \leq 120$

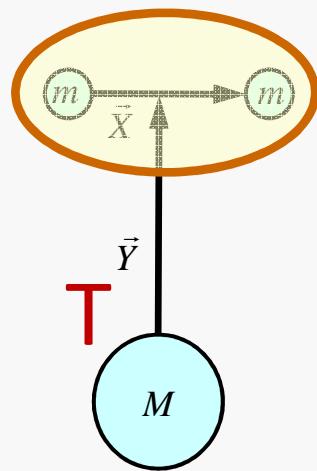

Erler et al., Nature 486 (2012) 509

Diproton model

- By simplifying interactions in the *core+p+p* system, the three-body decay can be reduced to the combination of two-body processes.

Jacobi T system → **diproton model**

The WKB approximation

$$\Gamma_{2p,dipr} = \theta_{dipr}^2 \mathcal{N} \frac{\hbar^2}{4\mu} \exp \left[-2 \int_{r_{in}}^{r_{out}} k(r) dr \right]$$

$$\mathcal{N} \int_{r_1}^{r_{in}} \frac{dr}{2k(r)} = 1 \quad k(r) = \sqrt{2\mu |Q_{2p} - 2V_p(r)|}$$

$$\theta_{dipr}^2 = \frac{(2n)!}{2^{2n} (n!)^2} \left[\frac{A}{A-2} \right]^{2n} O^2 \quad n \approx (3Z)^{1/3} - 1$$

The value of proton overlap function determined from the experimental half-lives of known 2p emitters: ^{19}Mg , ^{45}Fe , ^{48}Ni , and ^{54}Zn

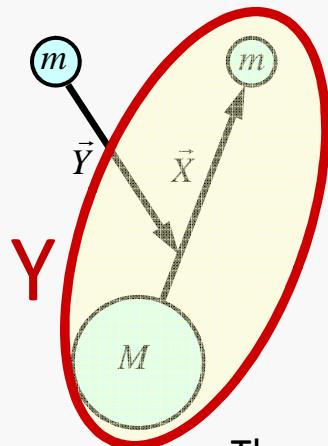

$$O^2 = 0.015$$

Direct model

Jacobi Y system → **direct model**

$$\Gamma_{2p,dir} = \frac{Q_{2p}}{2\pi} (Q_{2p} - 2E_p)^2 \int_0^1 d\varepsilon \frac{\Gamma_x(\varepsilon Q_{2p})}{(\varepsilon Q_{2p} - E_p)^2 + \Gamma_x(\varepsilon Q_{2p})^2/4} \times \frac{\Gamma_y((1-\varepsilon)Q_{2p})}{((1-\varepsilon)Q_{2p} - E_p)^2 + \Gamma_y((1-\varepsilon)Q_{2p})^2/4}$$

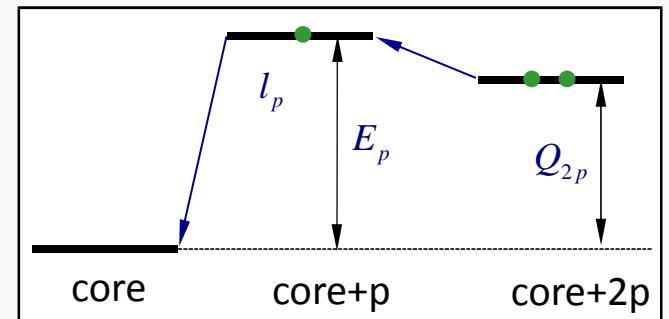

The value of spectroscopic factor determined from the experimental half-lives of known 2p emitters:
 ^{19}Mg , ^{45}Fe , ^{48}Ni , and ^{54}Zn , assuming $l_p = 0$

$$\theta_x^2 = \theta_y^2 = 0.173$$

Γ_i is the width of the two-body subsystem: $\Gamma_i(E) = 2\gamma_i^2 P_{l_p}(E, R, Z_i)$

$$\text{penetrability: } P_{l_p}(E, R, Z_i) = \frac{kR}{F_{l_p}^2(\eta, kR) + G_{l_p}^2(\eta, kR)}$$

$$\text{reduced width: } \gamma_i^2 = \frac{\hbar^2}{2\mu_i R^2} \theta_i^2$$

Grigorenko and Zhukov, PRC 76 (07) 014009
 M.P. et al, RMP (2012) 567

2p-emission half-lives

Direct model

$$\Gamma_{2p,dir} \equiv \frac{8Q_{2p}}{\pi(Q_{2p} - 2E_p)^2} \int_0^1 d\varepsilon \Gamma_x(\varepsilon Q_{2p}) \Gamma_y((1-\varepsilon)Q_{2p})$$

Diproton model

$$\Gamma_{2p,dipr} = \theta_{dipr}^2 N \frac{\hbar^2}{4\mu} \exp \left[-2 \int_{r_{in}}^{r_{out}} k(r) dr \right]$$

► The comparison of predicted half-lives with experiment

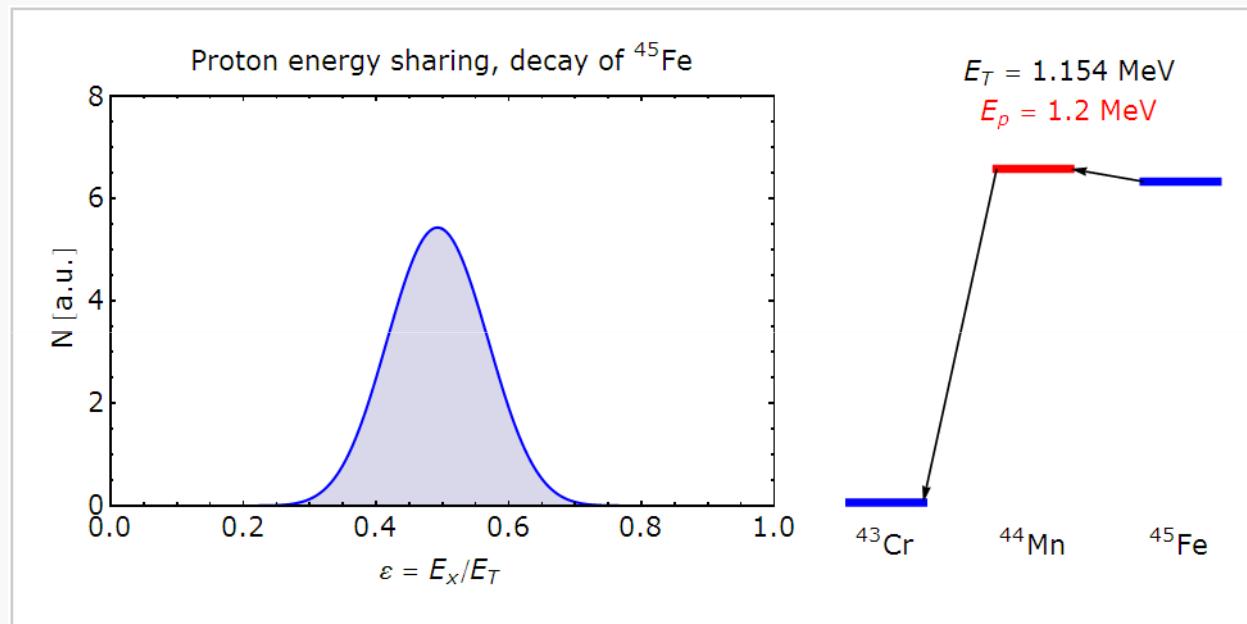

$$T_{1/2} = \frac{\ln 2 \hbar}{\Gamma}$$

$$l_p = 0$$

Nucleus	Experiment	Direct	Diproton
^{19}Mg [7]	4.0(15) ps	6.2 ps	12.3 ps
^{45}Fe [10]	3.7(4) ms	1.1 ms	8.7 ms
^{48}Ni [8]	$3.0^{+2.2}_{-1.2}$ ms	6.8 ms	5.3 ms
^{54}Zn [9]	$1.98^{+0.73}_{-0.41}$ ms	1.0 ms	0.8 ms

Simultaneous vs. sequential

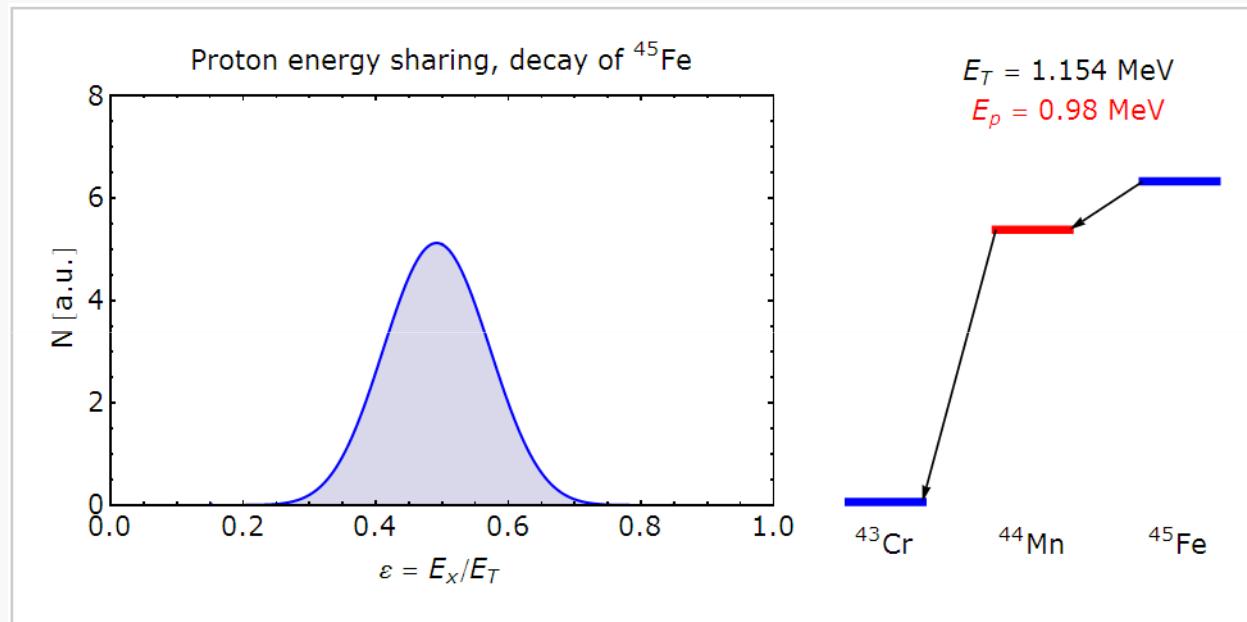

- ▶ In the direct model we can investigate how the proton's energy spectrum depends on the position of the intermediate state

$Q_{2p} = 1.15 \text{ MeV}, Q_{1p} = -0.05 \text{ MeV}$ ➔ True 2p decay (simultaneous)

Simultaneous vs. sequential

- ▶ In the direct model we can investigate how the proton's energy spectrum depends on the position of the intermediate state

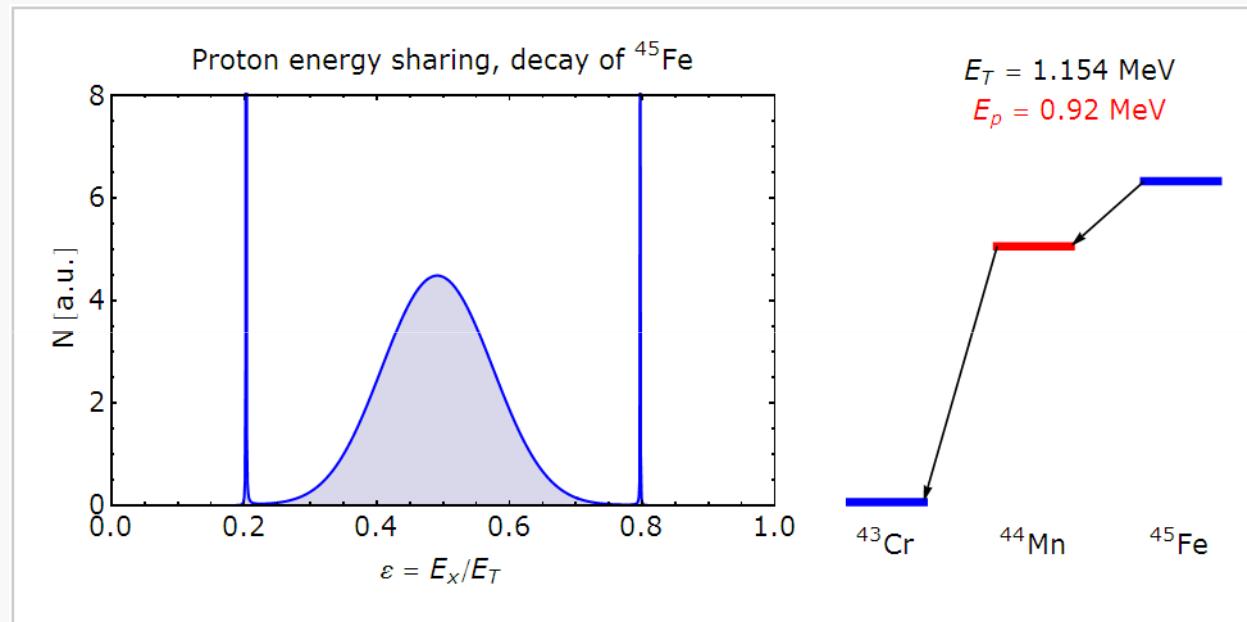

$$Q_{2p} = 1.15 \text{ MeV}, \quad Q_{1p} = 0.17 \text{ MeV}$$

➡ Still simultaneous 2p!

Simultaneous vs. sequential

- ▶ In the direct model we can investigate how the proton's energy spectrum depends on the position of the intermediate state

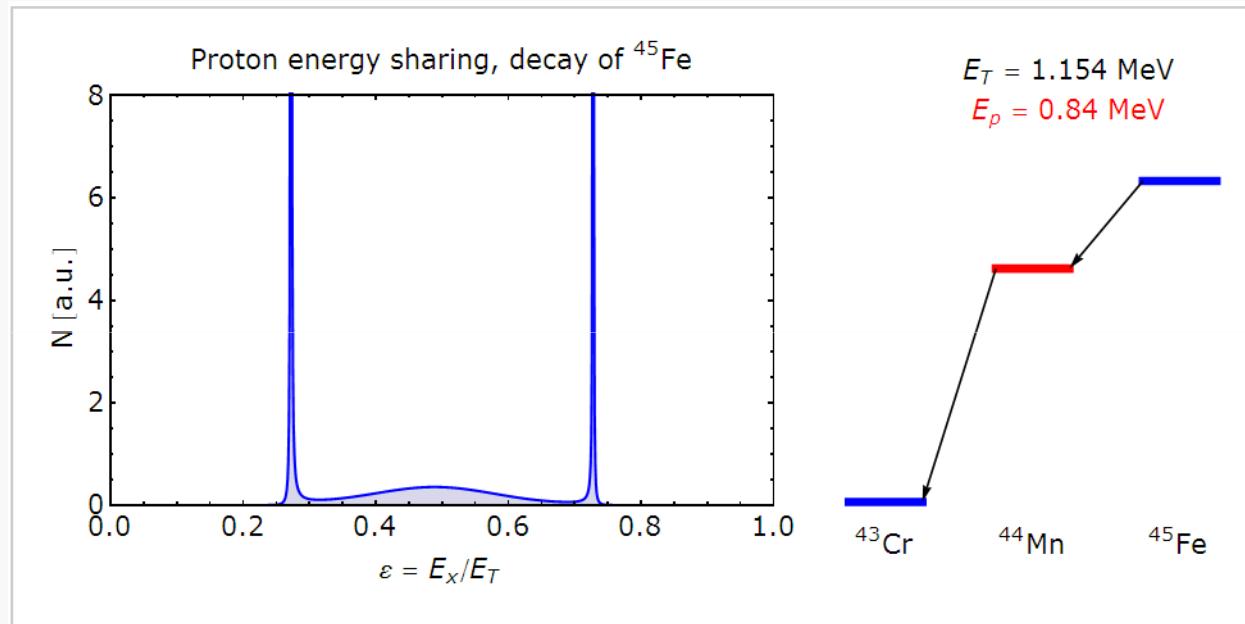

$$Q_{2p} = 1.15 \text{ MeV}, \quad Q_{1p} = 0.23 \text{ MeV}$$

➡ Sequential emission shows up!
Simultaneous component still visible.

Simultaneous vs. sequential

- ▶ In the direct model we can investigate how the proton's energy spectrum depends on the position of the intermediate state

$$Q_{2p} = 1.15 \text{ MeV}, \quad Q_{1p} = 0.31 \text{ MeV}$$

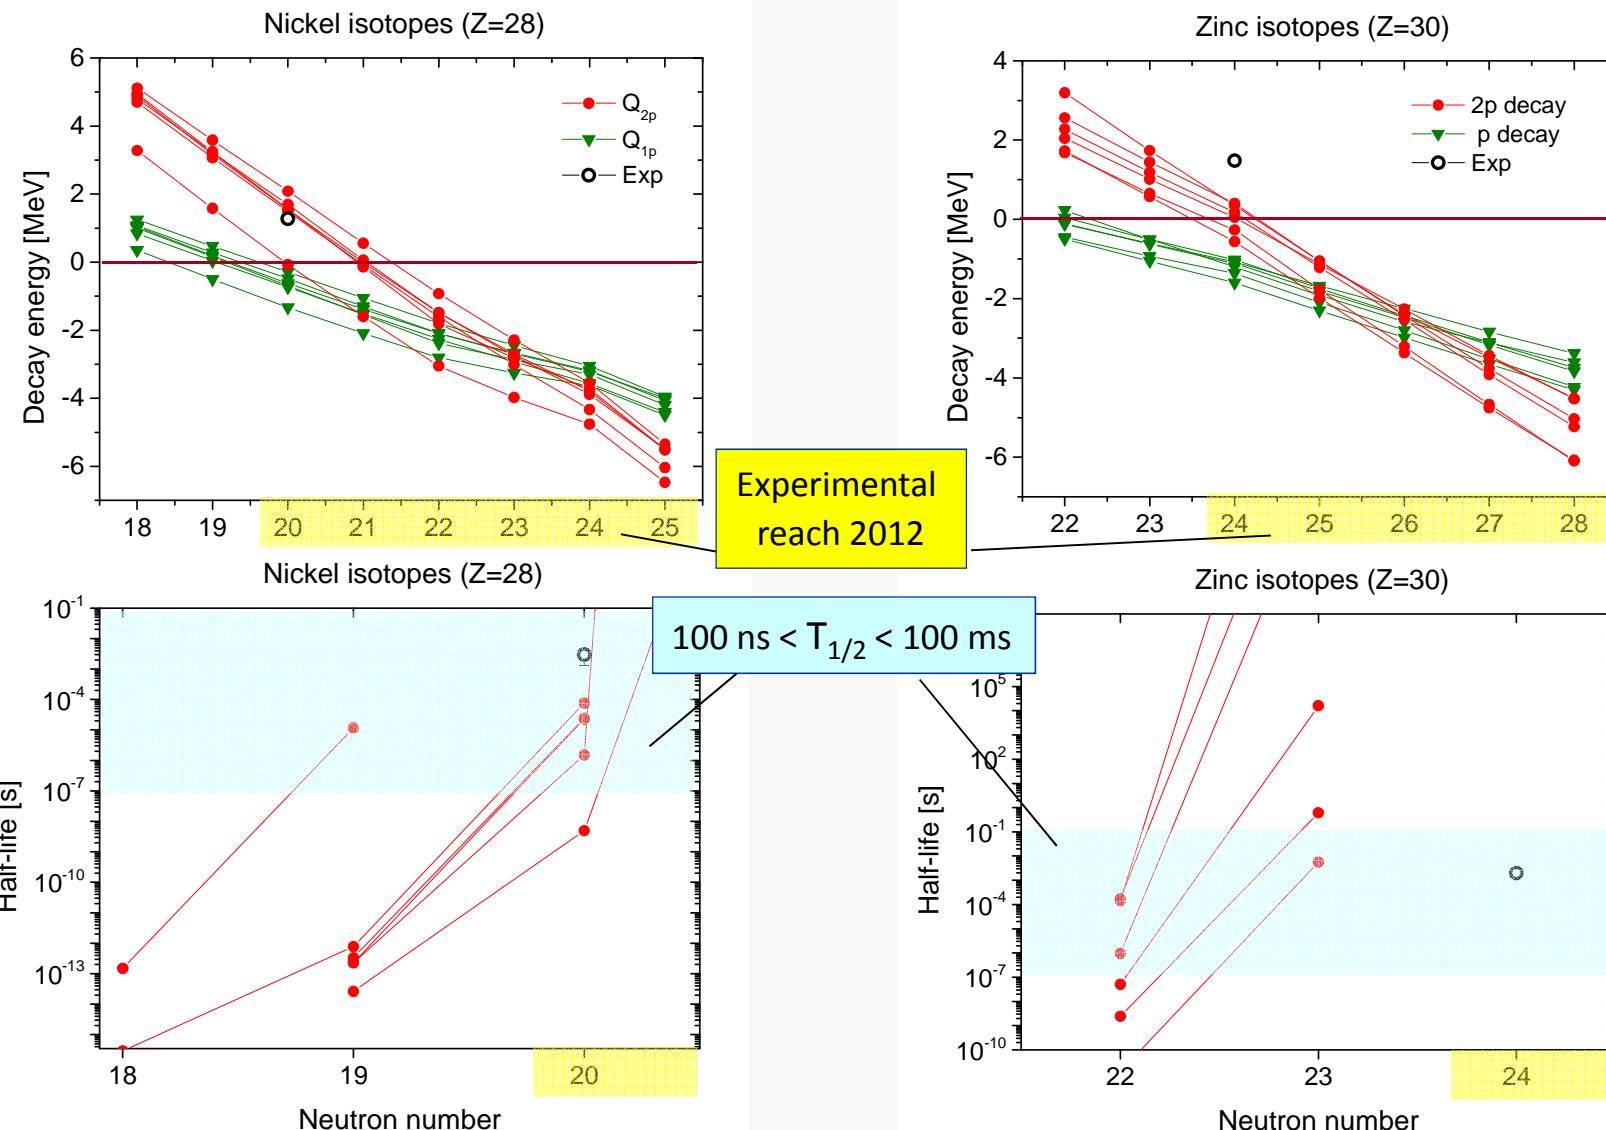

→ Sequential 2p emission dominates

→ Rough criterion: for $Q_p < 0.2 Q_{2p}$ true, simultaneous 2p decay
for $Q_p > 0.2 Q_{2p}$ sequential 2p emission

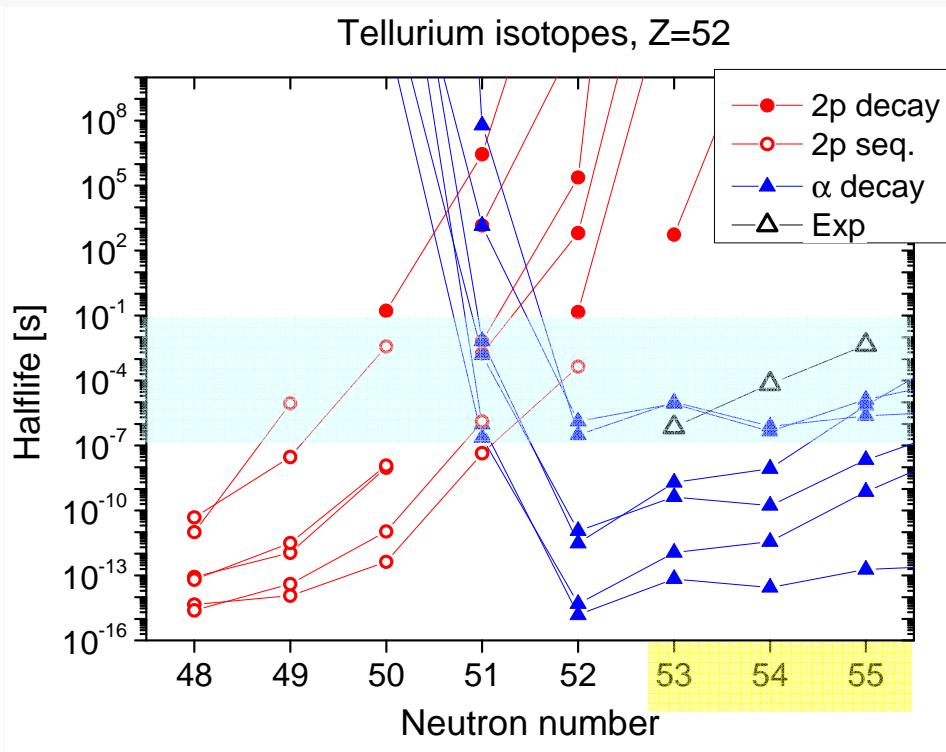

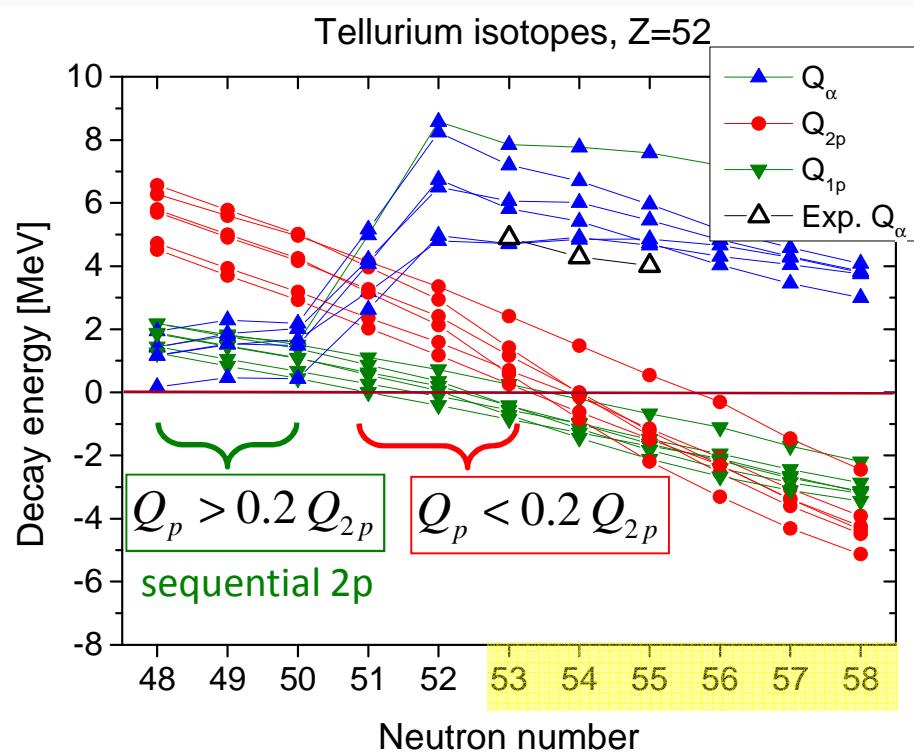

Predictions

- Nuclear binding energies: deformed DFT with six effective Skyrme interaction plus density-dependent zero-range pairing term ([Erler et al., Nature 486 \(2012\) 509](#))
- The half-lives for 2p emission: estimated with the direct and diproton models. The α decay half-lives calculated using global, fenomenological formula by [Koura, J. Nucl. Science and Tech. 49 \(2012\) 816](#)
- The adopted decay-time criterion (arbitrary): we consider a nucleus to be a **2p decay candidate** predicted by a given mass (and decay) model when $100 \text{ ns} < T_{1/2} < 100 \text{ ms}$. Longer half-life will loose competition with β decay. Shorter will be difficult to detect using in-flight separation and implantation technique.
- Counting:
a candidate has the model multiplicity $m(Z,N) = k$
when it is predicted by k mass models.

Nickel and zinc in the direct model

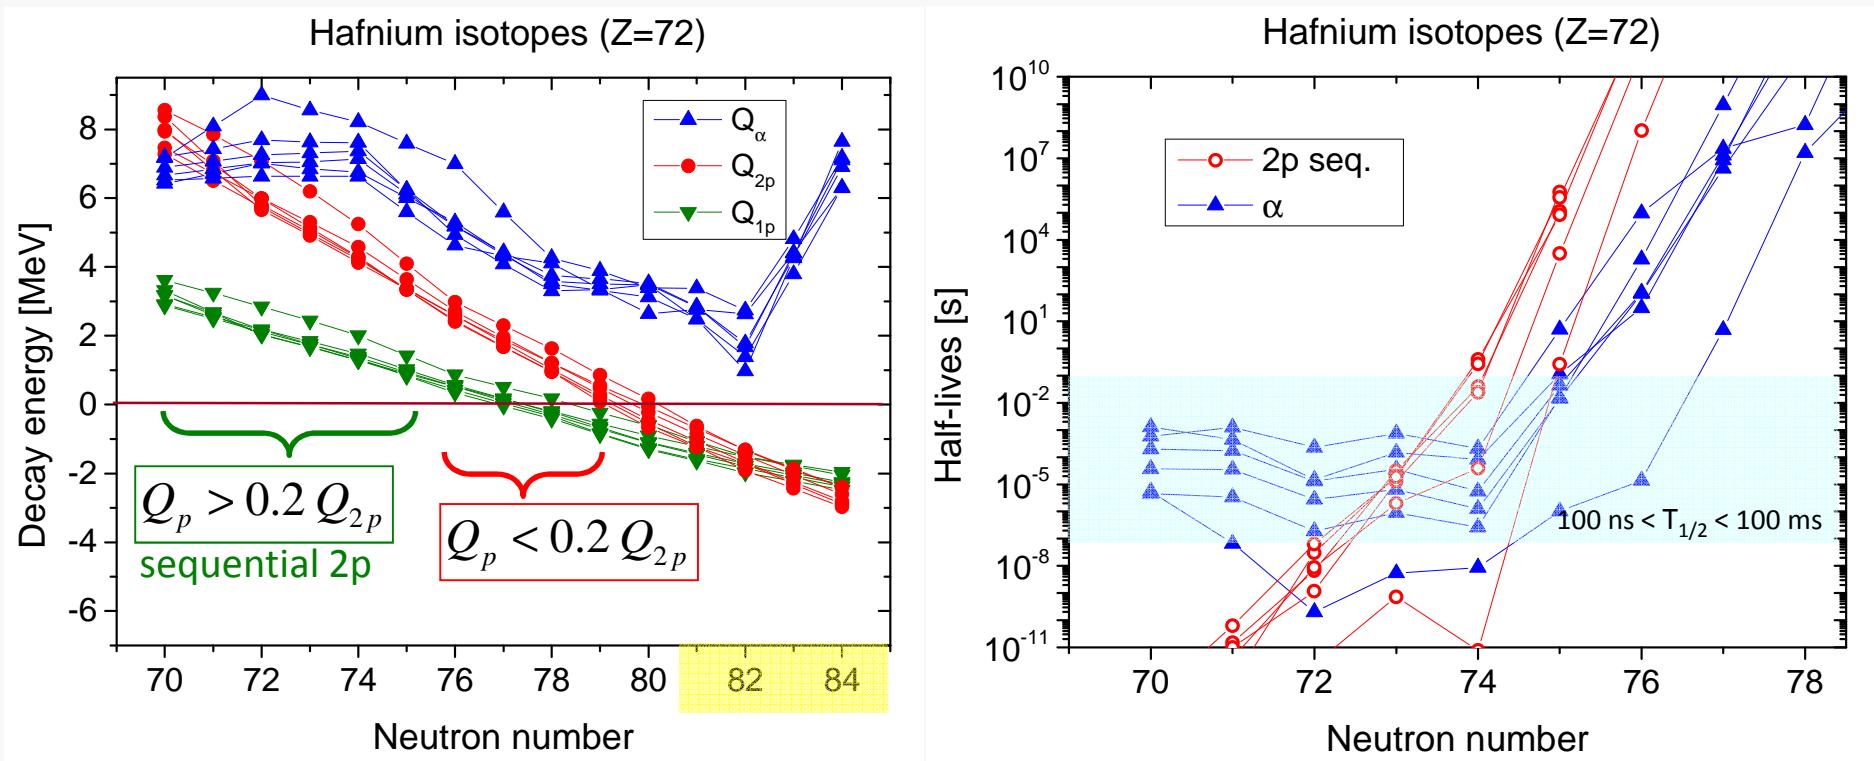

Tellurium

▲ α decay half-lives from the global, phenomenological formula by Koura, J. Nucl. Science and Tech. 49 (2012) 816

- At ^{103}Te a transition from the simultaneous 2p to the sequential emission occurs
- In addition, in ^{103}Te both decays, α and 2p may be observable!

No 2p above tellurium!?

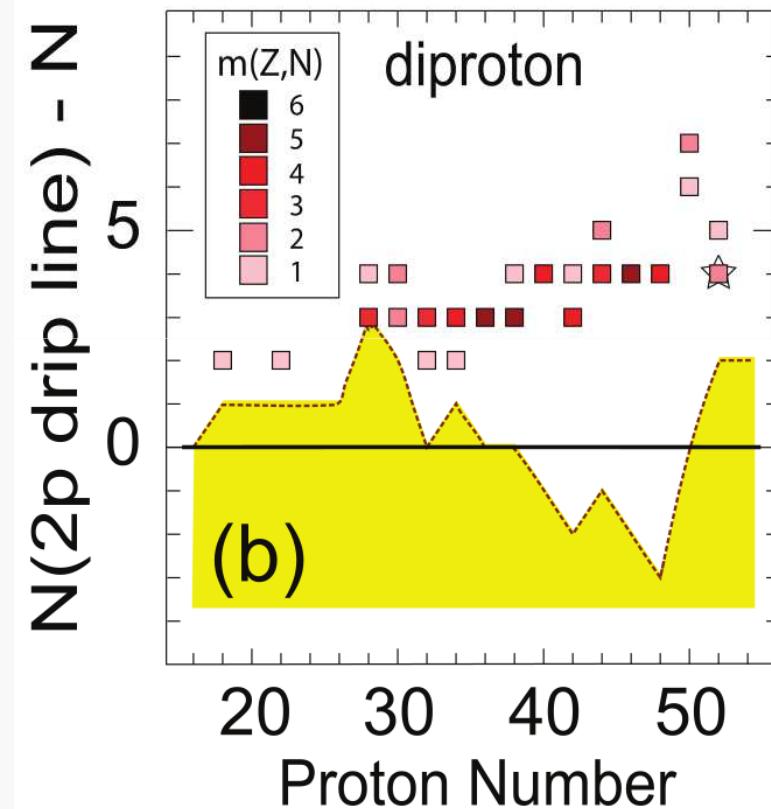

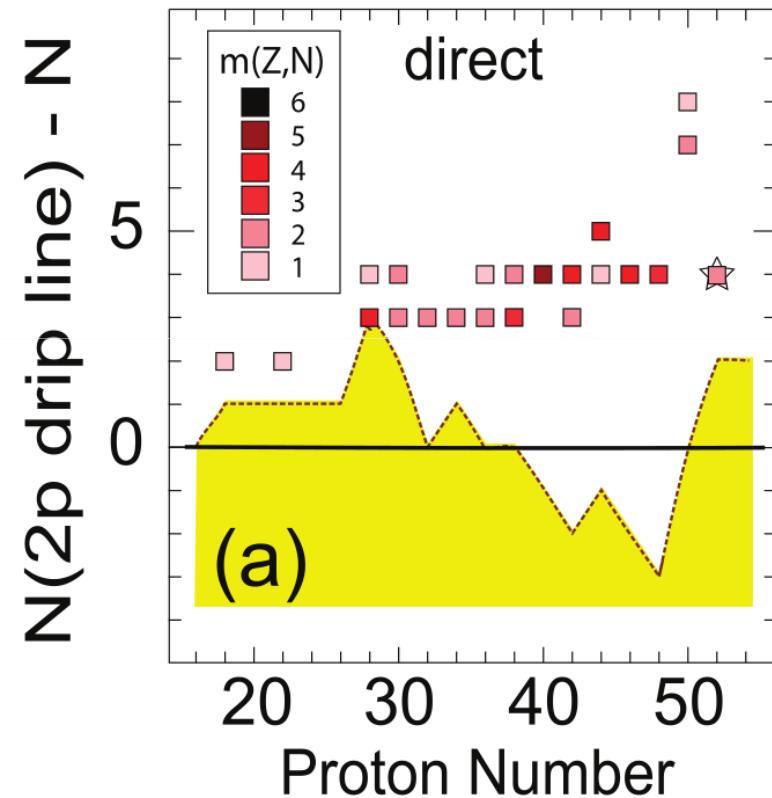

- When the energy condition for the true 2p decay is fulfilled, the predicted half-life is extremely long
- When the fast proton emission becomes possible, it proceeds as the sequential 2p decay

True 2p landscape

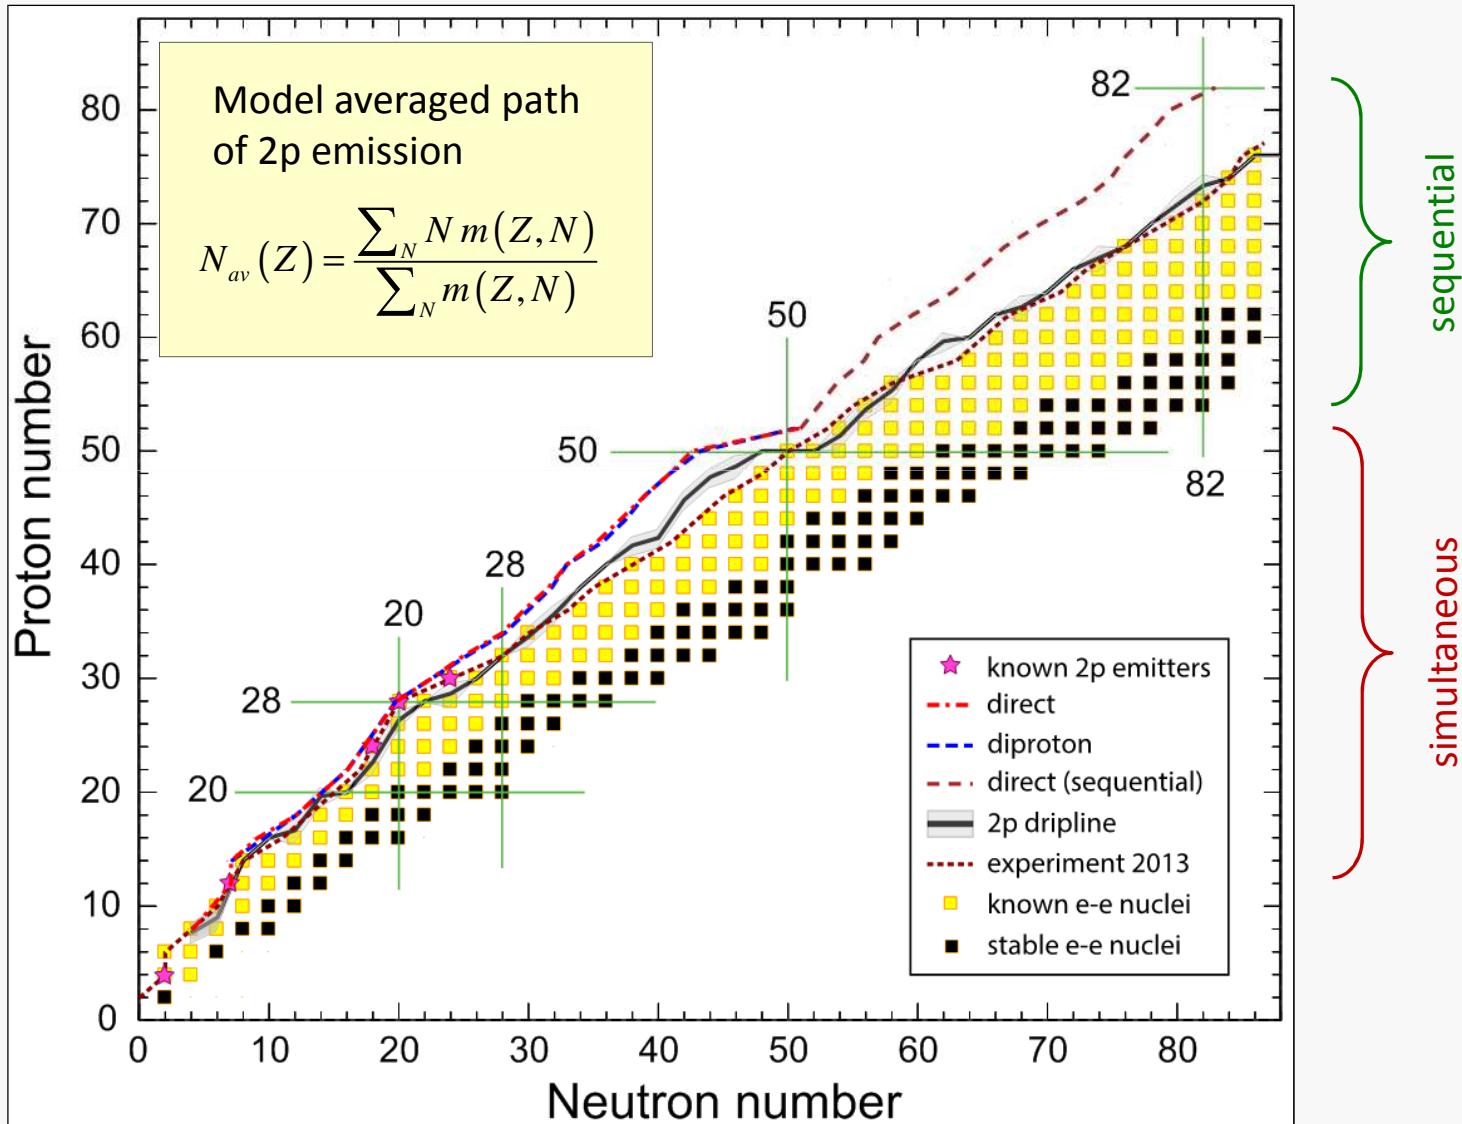

► Selection criteria:

$$100 \text{ ns} < T_{2p} < 100 \text{ ms}$$

$$T_{2p} < 10 \cdot T_\alpha$$

Full 2p landscape

Summary

- The direct (simultaneous) ground-state **2p emission established** for ^{6}Be , ^{19}Mg , ^{45}Fe , ^{48}Ni , and ^{54}Zn .
The hunt for other cases continues: ^{30}Ar , ^{59}Ge ,
- For every even-Z element between zinc and tellurium (Z=52) the isotopes decaying by 2p radioactivity in the time window $100 \text{ ns} < T_{1/2} < 100 \text{ ms}$ are predicted.
- In ^{103}Te the competition between simultaneous 2p, sequential 2p, and α emission may occur.
- Above tellurium the limit of decay spectroscopy is represented by sequential 2p emission, except for xenon (Z=54) where α decay dominates.
- Above lead (Z=82) α decay dominates, no 2p emission is expected to be observed.
